## Overview of the McNeill Dysphagia Therapy Program

The McNeill Dysphagia Therapy Program (MDTP) is a structured, intensive therapy designed to rehabilitate patients with swallowing difficulties caused by neurological and other disorders. Developed by Dr. Richard McNeill, the program uses a systematic approach to improve swallowing safety and efficiency through progressive exercises tailored to individual patient needs. It is widely regarded as an evidence-based intervention that enhances swallowing function and quality of life for patients with dysphagia.

# Principles of the McNeill Dysphagia Therapy Program

The core principles of the MDTP emphasize patient-specific exercise regimens that target the physiological components of swallowing. The program is built on the idea of neuroplasticity, encouraging repetitive and intensive practice to facilitate functional recovery. The therapy focuses on:

- Strengthening swallowing muscles
- Improving coordination and timing of swallowing
- Enhancing airway protection mechanisms
- Gradual progression of difficulty based on patient tolerance and performance

## Clinical Evidence Supporting MDTP

Multiple clinical studies have validated the effectiveness of the McNeill Dysphagia Therapy Program in various patient populations, including stroke survivors, head and neck cancer patients, and individuals with neurodegenerative diseases. The program's structured approach has been shown to reduce aspiration risk, improve nutritional status, and decrease dependence on feeding tubes.

Oropharyngeal Dysphagia is a common post-stroke complication associated with heightened morbidity and mortality. Research has established a relationship between reduced rate of SSF and OD. Methods: Three adult patients with OD underwent 15 sessions of MDTP. Clinical diagnosis of OD was established pre-treatment through Video fluoroscopic Swallow Study (VFSS) and Mann Assessment of Swallowing Ability (MANN). Functional Oral Intake Scale (FIOS) was employed to assess oral intake status. Participants' SSF per minute was recorded via recordings over 15 minutes. These assessments were conducted pre-treatment, post-treatment visit 16, and after a 3-week follow-up period. Results: All 3 participants with OD exhibited reduced SSF prior to MDTP. Following treatment, there was a noteworthy increase in SSF and noted improvement in clinical swallowing proficiency, functional oral intake, weight augmentation, and patient perception of swallowing ability post-MDTP. Conclusion: The use of MDTP offered improved utility in identifying
